MULTIPLEXER AND DEMULTIPLEXER

OBJECTIVES

After completing this experiment, you will be able to:
- Design and construct Multiplexer and DeMultiplexer
- Verify their truth tables using basic logic gates

COMPONENTS REQUIRED

- Two 7411, 3 I/P AND gates
- 7432, 2 I/P OR gate
- 7404, hex inverter

THEORY

MULTIPLEXER:

Multiplexer means transmitting a large number of information units over a smaller number of channels or lines. A digital multiplexer is a combinational circuit that selects binary information from one of many input lines and directs it to a single output line. The selection of a particular input line is controlled by a set of selection lines. Normally there are 2^n input line and n selection lines whose bit combination determine which input is selected.

DEMULTIPLEXER:

The function of Demultiplexer is in contrast to multiplexer function. It takes information from one line and distributes it to a given number of output lines. For this reason, the demultiplexer is also known as a data distributor. Decoder can also be used as demultiplexer.

In the 1x4 demultiplexer circuit, the data input line goes to all of the AND gates. The data select lines enable only one gate at a time and the data on the data input line will pass through the selected gate to the associated data output line.
